

epidermal cells plane; stomates superficial; druses present in the mesophyll cells; tabular crystal cells present.

This species appears to be allied to the widespread *Ficus trigona* L. f. It differs from that species in the greater number of lateral veins in the leaves (10 to 15 pairs *vs.* 3 to 9 pairs) and their lower angle of departure from the midrib; in the orifice of the fig not being surrounded by a raised rib of receptacular tissue; and in having the tepals of the flowers narrowly lanceolate (not hooded).

The species is known from three collections taken from a single tree between 1918 and 1922. I take pleasure in commemorating the name of the Senior Editor of the *Flora of Suriname*, who has been connected with studies of the Moraceae for more than thirty years.

TYPE SPECIMEN: Plantae Surinamenses, communicatae ex Herb. Acad. Rheno-traiect. Hab. Sectie O. Arbor no. 790, Coll. B.W.¹ no. 4639, d. d. 21-iv-1920 (A, holotype; U, isotype).

Additional specimens: data as above, B.W. 3639 (A, U); B.W. 5859 (A, U).

¹ B.W. = Collection made by the Forestry Bureau (Boschwezen).
